UTRGVTM

What to expect

- 1 Important definitions
- 2 Fibonacci polynomials
- 3 Golden polynomials
- 4 Our work - generalizing Golden polynomials
 - Forms
 - Patterns
- 5 Further study

Defining recursion

- a starting step
- how each step builds on each other
- when to stop stepping

Figure: The larger Russian dolls have room inside them for the smaller dolls; the larger recursive function defines smaller recursive functions inside of itself.

Recursion example - Fibonacci Numbers

Definition

Given $F_0 = 1$ and $F_1 = 1$, we define **Fibonacci numbers** as:

$$\forall n \geq 2 : F_n = F_{n-1} + F_{n-2}$$

For example:

$$F_2 = F_2 + F_1 = 1 + 1 = 2$$

$$F_3 = F_3 + F_2 = 2 + 1 = 3$$

$$F_4 = F_4 + F_3 = 3 + 2 = 5$$

$$F_5 = F_5 + F_4 = 5 + 3 = 8$$

Defining polynomials

- **poly** means many
- **nomial** means term

Polynomials are some function of x with many terms!

Defining recursive polynomials

- at least 1 starting term
- some function of x , usually defined by $\gamma(x)$, that builds on terms
- an $n \in \mathbb{N}$ that defines when the function stops

Figure: The arrangement of seeds in a sunflower can be described recursively

Fibonacci polynomials

Definition

Given initial conditions $F_0 = 1$ and $F_1 = x$ and $\gamma(x) = x$ as a function of x , define a **Fibonacci polynomial** as:

$$\forall n \geq 2 : F_n(x) = x * F_{n-1}(x) + F_{n-2}(x)$$

For Example:

$$F_2 = x^2 + 1$$

$$F_3 = x^3 + 2x$$

$$F_4 = x^4 + 3x^2 + 3x$$

$$F_5 = x^5 + 4x^3 + 3x$$

Formula for Fibonacci polynomials

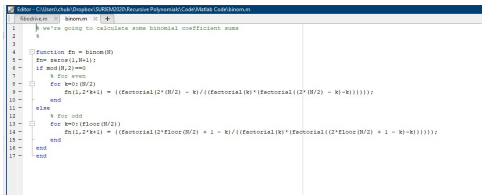

Below are formulas that generate even indices of Fibonacci polynomials:

$$F_{2n}(x) = \sum_{k=0}^{k=n} \binom{2n-k}{k} x^{2n-2k}$$

Binomial expansion

$$F_{2n} = \sum_{k=0}^{k=n} \frac{1}{k!} * \frac{d^k}{dx^k} (x^{2n-k})$$

Taylor expansion

A screenshot of a MATLAB script editor window. The title bar reads 'Editor - C:\Users\chub\Documents\MATLAB\FibonacciPolynomialCode\Matlab Code\Fibonacci'. The script content is as follows:

```
1 % we're going to calculate some binomial coefficient sums
2
3
4 function fn = binom(N)
5     %w zeros(1,N+1);
6     if mod(N,2)==0
7         % for even
8         for k=0:(N/2)
9             fn(1,2*k+1) = (factorial(2*(N/2) - k) / (factorial(k) * factorial((2*(N/2) - k) - k)));
10        end
11    else
12        % for odd
13        for k=0:(floor(N/2))
14            fn(1,2*k+1) = (factorial(2*floor(N/2) + 1 - k) / (factorial(k) * factorial((2*floor(N/2) + 1 - k) - k)));
15        end
16    end
17 end
```

Figure: MATLAB code verified results

Roots for Fibonacci polynomials

The following formula represents the exact expression of roots of $F_n(x)$:

When $F_n(x) = 0$:

$$x = 2i \cos \frac{k\pi}{n}$$

for $k = 1, 2, 3, \dots, n - 1$

Hogatt discovered this unique result for Fibonacci polynomials.

Golden polynomials

Definition

Given initial conditions $G_0 = -1$ and $G_1 = x - 1$ and $\gamma(x) = x$ as a function of x , define **Golden polynomials** as:

$$\forall n \geq 2 : G_n(x) = x * G_{n-1}(x) + G_{n-2}(x)$$

For Example:

$$G_2 = x^2 - x - 1$$

$$G_3 = x^3 - x^2 - 1$$

$$G_4 = x^4 - x^3 + x^2 - 2x - 1$$

$$G_5 = x^5 - x^4 + 2x^3 - 3x^2 - x - 1$$

Roots for Golden polynomials

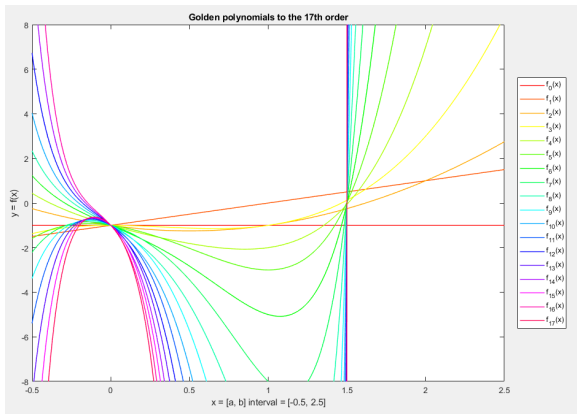

Figure: Moore found the limit of the maximum roots of $G_n(x)$ is $\frac{3}{2}$

Generalizing Golden polynomials

Alternate Definition

Given initial conditions $G_0 = -1$ and $G_1 = x - 1$ and $\gamma(x) = x$ as a function of x , redefine **Golden polynomials** as:

$$\begin{aligned}\forall n \geq 2 : G_n(x) &= x^1 * G_{n-1}(x) + x^0 * G_{n-2}(x) \\ &= x * G_{n-1}(x) + 1 * G_{n-2}(x) \\ &= x * G_{n-1}(x) + G_{n-2}(x)\end{aligned}$$

Then we can describe some function x^1 multiplied by $G_{n-1}(x)$ term, and some function x^0 multiplied by $G_{n-2}(x)$ term.

Generalized $G_n(x)$ in terms of k and l

Definition

With initial conditions $G_0(x) = -1$ and $G_1(x) = x - 1$, generalize the **Golden polynomials** as:

$$\forall n \geq 2 : G_n(x) = x^k * G_{n-1}(x) + x^l * G_{n-2}(x)$$

We have already shown the example for $k = 1$ and $l = 0$. When $k = l = 1$,

$$G_n(x) = x * (G_{n-1}(x) + G_{n-2}(x))$$

$G_n(x)$ for $k = l = 1$

$$G_0 = -1$$

$$G_1 = x - 1$$

$$G_2 = x^2 - 2x$$

$$G_3 = x^3 - x^2 - x$$

$$G_4 = x^4 - 3x^2$$

$$G_5 = x^5 + x^4 - 4x^3 - 2x^2$$

$$G_6 = x^6 + 2x^5 - 4x^4 - 4x^3$$

$$G_7 = x^7 + 3x^6 - 3x^5 - 8x^4 - x^3$$

$$G_8 = x^8 + 4x^7 - x^6 - 12x^5 - 5x^4$$

$$G_9 = x^9 + 5x^8 + 2x^7 - 15x^6 - 13x^5 - x^4$$

$$G_n(x) = F_{n-2}x^n - F_nx^{n-1}$$

General matrix representations of $G_n(x)$

Formula One:

$$\begin{bmatrix} G_{n+2}(x) & G_{n+1}(x) \\ G_{n+1}(x) & G_n(x) \end{bmatrix} = \begin{bmatrix} x^k & x^l \\ 1 & 0 \end{bmatrix}^{n-1} \begin{bmatrix} G_3(x) & G_2(x) \\ G_2(x) & G_1(x) \end{bmatrix}$$

Formula Two:

$$\begin{bmatrix} G_{n+4} & G_{n+3} & G_{n+2} \\ G_{n+3} & G_{n+2} & G_{n+1} \\ G_{n+2} & G_{n+1} & G_n \end{bmatrix} = \begin{bmatrix} x^k & x^l & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}^{n-1} \begin{bmatrix} G_5 & G_4 & G_3 \\ G_4 & G_3 & G_2 \\ G_3 & G_2 & G_1 \end{bmatrix}$$

Binet forms of $G_n(x)$ sequences

Sequence for $x = 2$:

| G_0 | G_1 | G_2 | G_3 | G_4 | G_5 | G_6 | G_7 | G_8 | G_9 | G_n |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| -1 | 1 | 0 | 2 | 4 | 12 | 32 | 88 | 240 | 656 | |

For Initial Conditions $G_0 = -1$ and $G_1 = 1$:

$$G_n = \left(\frac{\sqrt{3}}{3} - \frac{1}{2}\right)(1 + \sqrt{3})^n + \left(-\frac{\sqrt{3}}{3} - \frac{1}{2}\right)(1 - \sqrt{3})^n$$

Example for $n = 6$:

$$G_6 = \left(\frac{\sqrt{3}}{3} - \frac{1}{2}\right)(1 + \sqrt{3})^6 + \left(-\frac{\sqrt{3}}{3} - \frac{1}{2}\right)(1 - \sqrt{3})^6 = 32$$

Binet form to find $G_n(x)$ itself

The following formula produces the exact result for $G_n(x)$:

$$G_n(x) = \frac{\sqrt{x^2 + 4x} - 3x + 2}{-2\sqrt{x^2 + 4x}} \left(\frac{x + \sqrt{x^2 + 4x}}{2} \right)^n + \frac{\sqrt{x^2 + 4x} + 3x - 2}{-2\sqrt{x^2 + 4x}} \left(\frac{x - \sqrt{x^2 + 4x}}{2} \right)^n$$

Shifted Fibonacci numbers

We observed that when $x = 1$, we always yielded the negative Fibonacci numbers $\forall n \in \mathbb{N}$ where $n > 0$.

| G_1 | G_2 | G_3 | G_4 | G_5 | G_6 | G_7 | G_8 | G_n |
|--------|--------|--------|--------|--------|--------|--------|--------|------------|
| $-F_0$ | $-F_1$ | $-F_2$ | $-F_3$ | $-F_4$ | $-F_5$ | $-F_6$ | $-F_7$ | $-F_{n-1}$ |
| 0 | -1 | -1 | -2 | -3 | -5 | -8 | -13 | |

We observed this pattern persisted for cases where $k = l$.

More shifted Fibonacci numbers

Say $k = 2$, $l = 4$, and $x = -1$. Then we get:

| | | | | | | | | |
|--------|--------|--------|--------|--------|--------|--------|--------|------------|
| G_0 | G_1 | G_2 | G_3 | G_4 | G_5 | G_6 | G_7 | G_n |
| $-F_2$ | $-F_3$ | $-F_4$ | $-F_5$ | $-F_6$ | $-F_7$ | $-F_8$ | $-F_9$ | $-F_{n+2}$ |
| -1 | -2 | -3 | -5 | -8 | -13 | -21 | -34 | |

The pattern seems to hold whenever k and l are even, and $x = -1$.

Shifted Lucas numbers

Take this example where $k = 1$, $l = 2$ and $x = -1$:

| G_1 | G_2 | G_3 | G_4 | G_5 | G_6 | G_7 | G_8 | G_n |
|--------|-------|--------|-------|--------|-------|--------|-------|--------------------|
| $-L_0$ | L_1 | $-L_2$ | L_3 | $-L_4$ | L_5 | $-L_6$ | L_7 | $(-1)^n * L_{n-1}$ |
| -2 | 1 | -3 | 4 | -7 | 11 | -18 | 29 | |

The pattern seems to hold when k is **odd**, l is **even**, and $x = -1$.

Cyclical sequences - 3 terms

What if we plug in $x = -1$ instead?:

| G_0 | G_1 | G_2 | G_3 | G_4 | G_5 | G_6 | G_7 | G_8 | G_n |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|--|
| -1 | -2 | 3 | -1 | -2 | 3 | -1 | -2 | 3 | $G_{3n} = -1$ $G_{3n+1} = -2$ $G_{3n+2} = 3$ |

This seems to hold whenever k and l are odd and $x = -1$.

Cyclical sequences - 6 terms

Now let's look at the opposite, $k = 2$ and $l = 1$ for $x = -1$:

| G_0 | G_1 | G_2 | G_3 | G_4 | G_5 | G_6 | G_7 | G_8 | G_n |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-----------------|
| -1 | -2 | -1 | 1 | 2 | 1 | -1 | -2 | -1 | $G_{6n} = -1$ |
| | | | | | | | | | $G_{6n+1} = -2$ |
| | | | | | | | | | $G_{6n+2} = -1$ |
| | | | | | | | | | $G_{6n+3} = 1$ |
| | | | | | | | | | $G_{6n+4} = 2$ |
| | | | | | | | | | $G_{6n+5} = 1$ |

The pattern seems to hold so long as k is even, l is odd, and $x = -1$.

Ratios between $G_n(x)$ sequences

To explain our next results, we will introduce a new notation.

$$\lim_{n \rightarrow \infty} \frac{G_{n+1}(x)}{G_n(x)} = ???$$

Continued fraction notation - linear form

| Number | Also known as | As a continued fraction |
|-------------------|---------------|-----------------------------------|
| 1.5 | $\frac{3}{2}$ | $[1; 2]$ |
| $2.\overline{66}$ | $\frac{8}{3}$ | $[2; 1, 2]$ |
| 3.1415... | π | $[3; 7, 15, 1, 292, 1, 1, \dots]$ |
| 1.4141... | $\sqrt{2}$ | $[1; \overline{2}]$ |

Continued fraction example - ϕ

$$\phi = 1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{\dots}}}}$$

In linear form ϕ is expressed as

$$[1; 1, 1, 1, 1, 1, 1, \dots] \iff [1; \bar{1}]$$

Results for $k = l = 1$ - golden numbers

| x | $\lim_{n \rightarrow \infty} \frac{G_{n+1}(x)}{G_n(x)}$ | Continued fraction form |
|-----|---|-------------------------|
| 1 | 1.618034 | $[1; \overline{1}]$ |

| 3 | 9.321825 | $[9; \overline{3, 9}]$ |
| 4 | 16.24621 | $[16; \overline{4, 16}]$ |
| 5 | 25.19842 | $[25; \overline{5, 25}]$ |
| 6 | 36.16590 | $[36; \overline{6, 36}]$ |
| 7 | 49.14244 | $[49; \overline{7, 49}]$ |

Conjecture $\forall x \in \mathbb{N} : k \neq l, k > l$

$$\lim_{n \rightarrow \infty} \frac{G_{n+1}(x)}{G_n(x)} = [x^k; \overline{x^l, x^k}]$$

$$= x^k + \frac{1}{x^l + \frac{1}{x^k + \frac{1}{x^l + \frac{1}{x^k + \frac{1}{x^l + \dots}}}}}$$

Results for $k = 1, l = 2$

| x | $\lim_{n \rightarrow \infty} \frac{G_{n+1}(x)}{G_n(x)}$ | Alternate form |
|-----|---|----------------|
| 1 | 1.618034 | $1 * \Phi$ |
| 2 | 3.236068 | $2 * \Phi$ |
| 3 | 4.854098 | $3 * \Phi$ |
| 4 | 6.472134 | $4 * \Phi$ |
| 5 | 8.090168 | $5 * \Phi$ |
| 6 | 9.708202 | $6 * \Phi$ |
| 7 | 11.32623 | $7 * \Phi$ |

Conjecture $\forall x \in \mathbb{N} : k = 1, l = 2$

$$\lim_{n \rightarrow \infty} \frac{G_{n+1}(x)}{G_n(x)} = x * \Phi$$

These results are also conjectured about $\forall x \in \mathbb{Z}$.

Other interesting results for negative x will continue to be researched, observed and conjectured about further.

Utility of the generalized $G_n(x)$

Generalizing $G_n(x)$ allows us to make conclusions about its max root g_n . Similar to Moore we

- looked for a pattern - graphing and calculating $G_n(x)$
- proved existence of roots - using sequences to support the claim
- identified whether g_n was increasing, decreasing - or both

Root for $k = 2$ and $l = 1$

This is really cool - as $n \rightarrow \infty$ we see that the limit of the max root g_n of $G_n(x)$ approaches this quantity:

$$\frac{1}{1 - 2 * \sin\left(\frac{\pi}{18}\right)} \iff \frac{1}{p_c(\text{honeycomb bond})}$$

- This interesting quantity in the denominator is an exact quantity of what's referred to as $p_c(\text{honeycomb bond})$.
- This is a constant related to the field of percolation theory
- Determining an exact expression for other percolation thresholds, including of the square site percolation, remains an open problem - one which could be studied further with continued research of recursive polynomials - and a nice hot cup of coffee!

Root for $k = 1$ and $l = 2$

This is really cool - as $n \rightarrow \infty$ we see that the limit of the max root g_n of $G_n(x)$ approaches this quantity - though convergence is not as obvious:

$$\phi + 2 \iff \frac{3 + \sqrt{5}}{2} \iff [2; \bar{1}] \iff 2 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{\dots}}}}$$

- For fun we checked a couple of other cases keeping $k = 1$ but increasing l , unfortunately the pattern did not continue.
- This can be explained by the unique quality of the $k = 1$ and $l = 2$ case where there are only ever 2 terms.
- Increasing l creates more terms, which in turn, creates more roots that breaks the identified pattern

Concluding remarks

With continued research, we seek to:

- Generalize the behavior of sequences and the ratio between sequences for a recursive polynomial, based on the parity of k and l
- Extend matrix results to 4×4 , 5×5 , and up to $n \times n$ matrices
- Explore the existence of Pascal-3, Pascal-4, and up to Pascal- m type triangles for various k and l
- Characterize complex roots and the range in which the entirety of roots of G_n can be found
